Abstract: Cyclic voltammetry can be used to determine the relative stability of $Ce^{4+/3+}$ complexes which has been less accessible by other techniques. Shifts in the anodic and cathodic peak potentials of $Ce^{4+/3+}$ -L and the reversibility of the electrochemical processes were studied as a function of concentration of the ligands. The cyclic voltammograms of $Ce^{4+/3+}$ obtained at different scan rates are quasireversible with a formal redox potential of $E_{1/2}$ = 0.95975 V in 0.5 M H_2SO_4 solution. The voltammograms of $Ce^{4+/3+}$ -glycyl-glycine ($Ce^{4+/3+}$ -gly gly) and $Ce^{4+/3+}$ - glycyl- valine ($Ce^{4+/3+}$ -gly val) show a reduction wave negatively shifted relative to the reduction wave of $Ce^{4+/3+}$. The reversibility of the Ce^{4+}/Ce^{3+} couple improved with the increase of scan rates.

Key words: Cyclic Voltammetry · Stability Constant · Half-Wave Potential · Glycyl-valine and Glycyl-Glycine

INTRODUCTION

Peptides are an amazing class of compounds. Although they are all constructed from relatively simple building blocks (the amino acids), they exhibit a remarkable range of biological properties: peptides can act as antibiotics, hormones, food additives, poisons, or painkillers and it is primarily because of their medicinal properties that the study of peptides has become one of the most active areas of current research. When two amino acids are covalently linked together by amide bonds, the resulting molecules are called dipeptides [1] .The interaction between amino acids, peptides and proteins with metal ions plays an important role in biochemistry and biology and has been studied extensively during the last three decades. Complexes of amino acids and oligopeptides are involved in the exchange and transport mechanism of some trace metal ions in the human body [2-5]. The Ce4+/Ce3+ couple was chosen as the positive electrolyte of cerium (Ce4+/Ce3+) redox flow cell [6,7] mainly for the high potential of Ce4+/Ce3+ couple.

The reduction of Ce⁴⁺ at Pt, Au, Ir [8,9] highly boron-doped conductive diamond electrodes [9,10] and the oxidation of Ce³⁺ on Au, GC [11,12], PbO₂ [13,14], SnO₂ [15] electrodes were investigated. Klekens *et al.* [16] reported that the reduction of Ce⁴⁺ was independent of the electrode materials; the charge-transfer coefficient (α) and the heterogeneous rate constant (k_c) were similar for different electrodes, for instance, at Pt, Au, GC electrodes the k_c was 3.7×10^{-4} cm.s⁻¹ [19], 4.8×10^{-4} cm.s⁻¹ [20], 3.8×10^{-4} cm.s⁻¹ [17] and α was 0.21 [17], 0.35 [18], 0.28 [19], respectively. But, as to the oxidation of Ce³⁺, the various electrodes had different effects on the following reaction:

$$Ce^{3+} \rightarrow Ce^{4+} + e^{-}$$
 (1)

Here, H₂SO₄ was chosen as the acid media mainly because:

In HClO₄ or HNO₃ solution, the potential of Ce⁴⁺/Ce³⁺ couple is high and far above the over-potential for oxygen evolution and the Ce⁴⁺/Ce³⁺ couple is not stable in HClO₄ or HNO₃ solution [19,20]. Although

the potential of the Ce^{4+}/Ce^{3+} couple is also high in H_2SO_4 solution, Kunz [21] proved that $Ce(SO_4)_2$ could stably exist in H_2SO_4 solution, redox reaction seldom took place and the stability of the electrochemical active material is especially important in a redox flow cell.

- ClO₄ and NO₃ can not form stable complexes with Ce⁴⁺ and Ce³⁺ (this is also the reason that the potential of this couple is higher than that in H₂SO₄ solution). However, SO₄²⁻ can form a complex with Ce⁴⁺, in the form of CeSO₄²⁺, Ce(SO₄)₂ and Ce(SO₄)₃²⁻ [10]. Because of the formation of a stable complex, it was generally accepted that the Ce⁴⁺ and Ce³⁺ would not undergo hydrolysis in H₂SO₄ solution.
- If trying to take HCl as the acid media, then Ce⁴⁺ would oxidize Cl⁻ to Cl₂. Mills [22] used the Ru, Ir oxide as the catalyst to accelerate this reaction, which demonstrated that the Ce⁴⁺/Ce³⁺ couple was unstable in HCl solution.

In H_2SO_4 solution, the Ce^{4+} could form the following complexes with SO_4^{2-} :

$$Ce^{4+} + HSO_4^{-} \rightleftharpoons CeSO_4^{2+} + H^+$$
 (2)

$$CeSO_4^{2+} + HSO_4^{-} \rightleftharpoons Ce(SO_4)_2 + H^+$$
 (3)

$$Ce(SO_4)_2 + HSO_4 = Ce(SO_4)_3^2$$
 (4)

In this study, the shifts in the anodic and cathodic peak potentials of $Ce^{4+/3+}$ -L and the reversibility of the electrochemical processes were studied as a function of concentration of the ligands. The cyclic voltammograms of $Ce^{4+/3+}$ obtained at different scan rates are quasireversible with a formal redox potential of $E_{1/2}$ = 0.95975 V in 0.5 M H SQ solution. The voltammograms of $Ce^{4+/3+}$ -glycyl-glycine ($Ce^{4+/3+}$ -gly gly) and $Ce^{4+/3+}$ - glycyl- valine ($Ce^{4+/3+}$ -gly val) show a reduction wave negatively shifted relative to the reduction wave of $Ce^{4+/3+}$. The reversibility of the Ce^{4+}/Ce^{3+} couple improved with the increase of scan rates.

Experimental Section

Reagents: All the chemicals used were of analytical reagent grade. Glycyl-glycine $(C_4H_8N_2O_3)$, (gly gly), glycyl-Lvaline $(C_7H_{14}N_2O_3)$, (gly val), sulfuric acid and ceric ammonium sulfate dihydrate were obtained from Merck and Sigma, respectively. The aqueous stock solutions of the peptides were freshly prepared daily.

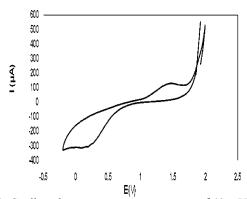

Fig. 1: Cyclic voltammograms at a scan rate of 40 mV/s for a glassy carbon electrode in a solution containing ce^{3+/4+} 0.1 M in aqueous 0.5 M H₂SO₄.

Electrode Preparation: A one-compartment electrochemical cell was used with a three-electrode configuration. Glassy carbon electrode was used as working electrode. The reference electrode was Ag/AgCl (saturated KCl) and the platinum gauze was used as the counter electrode. The working electrode was polished using 0.5 μ m of alumina for 2 min and rinsed with distilled water prior to each measurement.

Electrochemical Experimental: In cyclic voltammetry, CV, a cyclic voltammeter, Solartron 270, connected to a computer for automated data acquisition was used for current versus potential measurements. First, cyclic voltammogram of Ce4+/3+ 0.1 M in H2SO4 0.5 M was determined as shown in Figure 1. Then, the complexation of Ce4+/3+ by glycyl-valine and glycyl-glycine has been studied in different concentrations of the ligands $[(5\times10^{-4}, 8\times10^{-4}, 11\times10^{-4}, 14\times10^{-4}, 17\times10^{-4} \text{ and } 0.01) \text{ M}]$ in the same mixture of solvents accompanied by a gentle stirring and an nitrogen purge for 10 min prior to each measurement. All measurements were made at scan rates (20, 40, 60, 100 and 250) mV• s⁻¹. The half wave potential $(E_{1/2})$ values reported here are defined as the numerical average of the cathodic and anodic peak potentials. All electrochemical potentials measurements are expressed relative to the Ag/AgCl electrode.

RESULTS AND DISCUSSION

Cyclic voltammetry can be used to qualify the comparative stability of $Ce^{4+/3+}$ complexes which has been less available by other techniques. Shifts in the anodic and cathodic peak potentials of $Ce^{4+/3+}$ -L and the

Table 5: Average values of the formation constants of Ce-gly gly and Ce-gly val at 25 °C and constant ionic strength

	-
Species	log β ₁₀₁ *
Ce-gly gly	5.685
Ce-gly val	8,742

 $^{^*\}beta_{pqr} = [M_p H_q L_r^{(4p+q-r)}]/[M^{+4}]^p [H^+]^q [L]^r [23]$

reversibility of the electrochemical processes were determined as a function of concentration of the ligands. The cyclic voltammograms of Ce4+/3+-gly gly and Ce4+/3+gly val obtained at different scan rates are quasireversible with an average formal redox potential of E_{10} = 0.893 V and E_{10} = 0.834 V as shown in Tables 1 and 2, respectively. On the basis of the cyclic voltametry measurements described above, the electron transfer process is attributed to the Ce4+/3+-L redox couple. The effect of the scan rate on the shape of the cyclic voltammograms is shown in Figure 2 for Ce4+/3+-gly gly (the cyclic voltamograms Ce4+/3+-gly val have not shown). In the whole scan rate range, the cathodic peak potential is slightly shifted toward more cathodic potentials with increasing scan rate. The decrease of the cathodic peak potential (a few mV) could be due to a small error provoked by ohmic drop corrections and the uncertainty of the R. measurement. It can be mentioned that most of the other actinides have shown a reversible behavior at low scan range. The voltammograms of Ce4+/3+-gly val and Ce4+/3+-gly gly show a reduction wave negatively shifted relative to the reduction wave of Ce4+/3+ in deferent concentrations of ligand which as shown in Figures 3 and 4. The half-wave potential, E_{1/2}, of Ce^{4+/3+}-gly val and Ce^{4+/3+}-gly gly was found to be somewhat dependent on concentration of the ligands and these results can be simply explained by their interaction between the metal ion and each ligand which this results reported in Tables 3 and 4 at below. In Figures 3 and 4, a shift of $E_{1/2}$ of the $Ce^{4+/3+}$ -gly gly and $Ce^{4+/3+}$ -gly val couples to less negative values is observed when the concentration of each ligand is increased. The half-wave potentials, $E_{1/2}$, of the Ce^{4+/3+}, Ce^{4+/3+}-gly val and Ce^{4+/3+}-gly gly couples were determined according to the following equation:

$$E_{1/2} = E_{pa} - \Delta E_{p}/2 \tag{5}$$

where, $E_{\rm pa}$ is the anodic peak potential and $\triangle E_{\rm p}$ is the difference between the anodic and cathodic peak potentials ($\triangle E_{\rm p}$) = ($E_{\rm pa}$ - $E_{\rm po}$). The stability constants of Ce^{4+/3+}-gly val and Ce^{4+/3+}-gly gly were determined at 25 °C by plotting equation 6 to give m and the stability constant, log β , from the slope and the intercept, respectively.

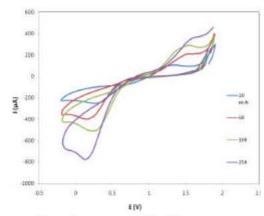

Fig. 2: Cyclic voltammograms in different scan rates for a glassy carbon electrode in a solution containing ce^{3+/4+} 0.1 M in aqueous 0.5 M H₂SO₄ 0.0008 M glycyl-glycine ligand.

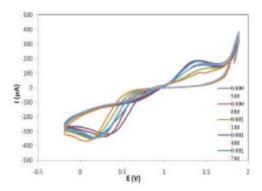

Fig. 4: Cyclic voltammograms at a scan rate of 40 mV/s for a glassy carbon electrode in a solution containing ce^{3+/4+} 0.1 M in aqueous 0.5 M H₂SO₄ and different concentrations of glycyl-Valine ligand

$$\Delta E_{1/2} = 0.0591/n (\log \beta + m \log[L])$$

where, m and n are the ratio of each ligand in the complex species and the electron transferred, respectively. $\Delta E_{1/2}$ is the half-wave potential difference between the metal ion and the complex $[\Delta E_{1/2} = E_{1/2} - E_{1/2}(L)]$. The results of the calculations and the cyclic voltammograms of $Ce^{4+/3+}$ -gly gly and $Ce^{4+/6}$ val systems are summarized in Table 5.

CONCLUSION

The stability constants of Ce4+/3+-gly gly and Ce4+/3+gly val, the redox potentials of the Ce4+/Ce3+ redox ion couple and the electrochemical behavior of the Ce4+/Ce3+ redox reaction were studied at different concentration of gly gly and gly val. As shown in Table 5, the stability constant Ce4+/3+-gly val is more than Ce4+/3+-gly gly. This case can be explain due to the more nucleophilic properties glycyl valine relative to glycyl glycine, as we can observe this subject in the thorium complexes with mentioned dipeptides [23]. According to ref 23, the stability constants values of Th(IV) ion at constant temperature (25°C) and constant ionic strength (0.1 mol.dm⁻³ sodium perchlorate) with gly gly and gly val determined by the potentiometric spectrophotometric titration methods.
